The Shocking Truth About Commercial Dog Food Revealed	28

Introduction

Whether you've just picked up your first puppy from the breeder or the kennel or you've been raising a dog for the past five years, the chance that you might face your dog's first illness is always present. As a dog owner, it is your responsibility to make sure your dog remains happy and healthy at all times.

To do that, you need to know exactly what actions you're taking now could lead to or prevent the common health problems that domestic canines face every year. Each breed is susceptible to different health problems, but if you spend time learning how to prevent and treat those issues now, you'll never need to worry about your dog being struck out of nowhere by any of the 20 ailments listed in this book.

Read carefully, take notes and make sure your dog never falls victim to any of these health issues. Remember that your dog cannot tell you when he doesn't feel well. The only way to properly treat these health problems is through prevention and early warning signs.

Before you continue reading... The Shocking Truth About Commercial Dog Food Revealed

<http://www.dogtrainingword.com/go/dogfood>

In this thought-provoking video, you will see exactly how many commercial dog food brands are killing pets all over the world.

See the evidence based on veterinary medical research that shows that any dog that eats commercial dog food is at a much higher risk of dying prematurely.

But don't worry, this video isn't all scary stories; there are also practical and proven solutions that you can start adopting today. Just one of the simple solutions in the video shows you how you can increase the lifespan of your dog by up to 134 percent while saving you up to \$10,000 over the lifetime of your dog.

Check out the video now, and prevent your dog from suffering an early and painful death:

Ear Infection

For a dog, an ear infection is a very real possibility — the result of ear mites, bacteria, food allergies, bad hygiene or an environmental factor that can get into his ear and cause problems. For the most part, ear infections need to be treated immediately by a veterinarian due to the very real threat they pose to your dog's health.

Warning Signs

An ear infection should be treated immediately when recognized, so you should be constantly watching for signs that your dog's ears are not healthy. Do this with a weekly or biweekly check of his ear canals and looking for signs of waxy discharge, red inflammation, constant scratching or general discomfort in your dog's behavior.

Who Gets Ear Infections

Ear infections are most common in dogs with floppy ears that do not get enough air. Moisture and dirt particles can get trapped in the ear, and an infection can quickly form if you are not careful.

Both fungus and yeast are common factors in ear infections due to the closed environment of a floppy-eared dog. Cocker Spaniels, bloodhounds, beagles, dachshunds and other floppy-eared dogs should be checked regularly for signs of potential infection.

Avoiding Infections

To avoid ear infections, check your dog's ears regularly for signs of an odor or abnormal discharge of wax. You can clean your dog's ears as well if they produce excess wax. Don't use anything with a sharp end. Use cotton balls with a dog-specific cleaning solution to ensure you don't make it worse or get any liquid trapped in their ears.

Avoid any over-the-counter medicines or remedies before checking with your vet. Even in prevention of ear infections, it is best to check with your vet first and ask what specific measures might be good for your breed of dog.

If your dog gets an ear infection, see a vet immediately as the chance that it could spread to a middle or inner-ear infection is too dangerous to risk. Inner-ear infections can spread to other parts of the body or create damaging high fevers.

Skin Allergy

Dogs are just as susceptible to allergies as human beings, and they don't have the benefit of going down to the store and picking up Claritin or Zyrtec. All they can do is lick, chew or scratch at the hot spots and marks they get on their skin as a result.

If your dog starts to show any of the signs of a skin allergy, the vet should be your first stop. However, there are many things you can do to avoid these issues cropping up at all.

Warning Signs

Skin allergies will appear in a few different forms. Allergies themselves are most frequently related to flea bites, followed by food allergies and then inhalant allergies, such as dust or pollens. The skin will often grow irritated and red. Swelling may occur but will most often be a result of excess scratching or biting by your dog.

If your dog starts to lose hair as a result of the reaction or gets an ear infection, it might be a long-term food allergy related to their dry food — a common problem that occurs in many dogs that eat processed dog foods.

Who Gets Skin Allergies

Any dog can come down with skin allergies. There is no particular indicator that makes a single dog more likely to get sick. However, dogs that are fed dry food too early do have a higher rate of food allergies, and short-haired dogs are more likely to suffer from skin-contact allergies.

Additionally, dogs that are bred for water sports or hunting tend to be less susceptible to flea bite allergies and moisture issues, though this is not exclusive. Any dog can suffer from dampness and flea bites.

Avoiding Skin Problems

Skin problems can be avoided in a number of ways. To start, make sure your dog is given flea medication on a regular basis. This is important not just for flea bite allergies, but also for avoiding potential sickness from tick bites or other parasites that will latch onto your dog when he goes outside.

Additionally, avoid feeding your dog foods with too many grain fillers. Of the grains, rice is the safest with corn, soy and wheat all directly linked to allergens that dogs can develop.

Processed meats can also cause food allergies, and table scraps should be strictly avoided due to the ingredients in them that a dog cannot process.

If your dog starts to show signs of skin problems for any reason, see your vet. He will likely take blood tests and possibly put your dog on an elimination diet to see how his allergic reactions respond. Very often, basic nutritional changes can be all a dog needs to get better.

Skin Infections and Hot Spots

While red spots and inflammation on a dog's skin might be caused by allergies, there are more severe skin problems that can develop in the form of actual infections or hot spots where fur recedes, swelling occurs and the dog starts to show signs of infection, such as reduced appetite, lethargy or general malaise.

Skin infections come in many forms. Superficial Pyoderma is the most common and the one your dog is most likely to experience — also known as hot spots. They are caused by the overgrowth of bacteria on the surface of the dog's skin and are avoidable and very easily treatable if caught early.

Warning Signs

There are not usually any warning signs of hot spots. They will show up one day and need to be treated immediately. A hot spot is usually indicated by circular patches where the hair is missing and the skin gets swollen, itchy and exudes pus.

The dog will often lick, bite and scratch to the point of causing injury or even bleeding to the area. Hot spots that are not treated promptly will often grow and make your dog very irritable and possibly sick.

Who Gets Hot Spots

Dogs most commonly susceptible to hot spots include those with heavy coats, histories of infections and allergies, fleas, problems with their anal sacs, grooming issues and hair tangles. Keep in mind, however, that even a perfectly healthy short-haired dog can get hot spots out of nowhere, so it is not a limited issue.

Humidity and warmth can increase the risk of hot spots due to trapped moisture, and an infection can be formed *after* a dog sheds because he licks too much. Hot spots will most commonly occur on the legs, backside, flanks and feet — the places where a dog can lick and bite most easily. Severe hot spots can also appear on the neck, ears and head.

Avoiding Infections

To avoid hot spots, target the cause of the problem and then treat it. If it is a grooming issue, make sure you're combing your dog as often as twice a day. If he has allergies, see a vet and get him treated for the allergies — either with a new diet or with antihistamines.

If the process seems to be psychological, you may need to get him more exercise and keep him busy, so he doesn't get so bored as to cause these infections.

Vomiting

Every dog vomits — probably a lot more often than we do. It is a natural method of removing any foreign bodies or debris that they may have ingested, something we know our dogs are all too eager to do on a regular basis. So, for the most part, you can ignore vomiting, but every now and then it can be a symptom of something much worse.

Warning Signs

Most often, if vomiting is a serious health issue, it is accompanied by other symptoms, including diarrhea, lethargy, behavioral problems and more. Additionally, if your dog vomits multiple times, it can be a sign of something worse. There are two forms of vomiting you need to be wary of.

If your dog vomits multiple times suddenly — acute vomiting — it could be a medical emergency and should be treated immediately. On the other hand, if your dog vomits every week or so like clockwork, it could be a chronic issue related to an allergy or illness.

Who Has Vomiting Problems

Vomiting does not relate to any one dog breed. Instead, it relates to the specific health problems a dog may have. Acute vomiting can be caused by a sudden change in diet or the ingestion of something your dog's body doesn't know how to digest. It can also result from quick ingestion of dry food. To avoid these issues, feed your dog in smaller meals more frequently and don't give him any table scraps.

Parasites and worms can also cause vomiting in your dog. Roundworms are particularly common causes of vomiting, along with Giardia and Coccidia, which will sometimes show in the feces or vomit.

If your dog vomits repeatedly suddenly, it could mean a foreign object blocks his digestive tract or he ingested a poison. See a vet immediately if this is the case. Bloating and a complete lack of movement will often accompany obstructions as well.

Avoiding Vomiting

There is no direct way to avoid vomiting. Don't give your dog table scraps, don't feed him large meals if he eats too fast, and don't let him play with anything that he could easily ingest if he gets too carried away. And, as always, see a vet immediately if your dog exhibits any signs of additional illness or vomits more than once successively.

Diarrhea

Nothing is more upsetting (for multiple reasons) than your dog getting diarrhea when you take him for a walk. The problem is that you never know for sure what may have caused the diarrhea or how you can treat it. So, the easiest way to handle it is to watch for any other symptoms and report to the vet anything you find.

Warning Signs

Diarrhea is often a sign of an upset intestinal tract or possible disease. The former is more common and can be the result of eating something unkind to a dog's body, worms or parasites, or anxiety.

It's important to look in the diarrhea for signs of worms and parasites, blood, mucous or strange colors that do not look natural. It is best to take a stool sample with you to the vet as well.

You may also notice that a dog will show signs of disease when he has diarrhea. Look for vomiting, depression, dehydration or any unwillingness to eat or drink.

Who Gets Diarrhea

Dogs get diarrhea for any number of reasons. Standard reasons that make a dog sick and you can control include feeding them food that doesn't fit in with their normal diet. Table scraps are an especially problematic source of diarrhea. They can also get sick from getting into the trash, eating other dog's feces, or simply having their food changed too suddenly.

Avoiding Diarrhea

If your dog gets diarrhea and has no other serious symptoms, start by withholding food (not water) for a day. This will allow the dog's digestive tract to settle and get back to normal. Then, reintroduce him to a bland diet of chicken and rice without any flavoring or additions (freshly cooked and cooled by you).

If the dog's feces return to normal, you've found the cause. If they do not, it is time to call the vet. Additionally, to avoid common causes, don't feed your dog table scraps, and if you change his food, do it slowly over time. Don't just suddenly change dry foods on him. Change it a quarter cup at a time to give his body time to react.

Bladder Infection

A bladder infection is a common internal infection that can be caused by bacteria getting into your dog's urinary tract, bladder or kidneys. At first, it can be very hard to identify the symptoms of a urinary infection in a dog, but with time, you'll be able to see that the dog is in a great deal of pain when he urinates and grows generally ill-tempered as a result of the pain. As an internal infection, however, if you ignore a bladder problem, it could progress to the other organs and possibly even become fatal.

Warning Signs

A dog will generally let you know if he is victim of a urinary infection. The dog will start needing to go to the bathroom much more often than normal. He might also start to whine or cry whenever he urinates, and it might appear that he is straining or pushing to pee.

The urine itself will not smell like ammonia, but will be fetid and unhealthy, possibly a different color. Blood and pus might also be in the urine if the infection has spread.

The dog will also lick his genitals for an extended period of time in many cases, and he might even urinate in the house due to the slow loss of control over his bodily functions. A fever can also develop, and if it is bad enough, kidney problems will follow.

Who Gets Bladder Infections

Any dog can get a urinary tract infection. It is one of the very unfortunate effects of peeing outside. Smaller dogs might be more susceptible due to their low position to the ground, and females have slightly higher rates due to how they pee. Generally, however, there are no indicators for how a bladder infection might occur.

Treating Infections

To treat a urinary tract infection in your dog, you'll likely need to see your vet immediately. Give your dog a lot of water with a bit of extra Vitamin C and citrus fruits added to it.

Walk your dog more often, so he doesn't have to hold any urine that builds up in his bladder, and if the vet provides antibiotics, administer them regularly. It is also believed that a vegetarian diet can be very helpful in reducing the infection, as it is low in nitrogen and will help speed up the healing process.

Arthritis

Like human beings, dogs can suffer from arthritis as they age, slowly developing a number of signs that they can no longer get up and enjoy the outdoors in the same way they always did.

There are some dogs that are more susceptible to arthritis, but all dogs may develop it as they age due to the nature of their joints, especially their hips and shoulders.

Warning Signs

The most common dogs to develop arthritis are those that grow overweight and don't get enough exercise. Additionally, younger dogs can get arthritis if they sustain an injury that puts undue stress on the joints. Hip dysplasia is a major issue for many dogs that results in arthritis so bad they cannot move.

Osteoarthritis is the most common form of arthritis and results from the breakdown of cartilage from overuse. When your dog gets older, watch for any signs that he is losing his full range of motion.

If he slows down, cannot get up stairs or has trouble getting into the car at any point, you should see a vet to determine the extent of the arthritis and if the dog needs medication or aids to live life as normal.

Who Gets Arthritis

All dogs get arthritis at some point in life, but dogs that overeat and put undue stress on their joints can suffer much more from it than others. If your dog is overweight, especially in old age, consider a diet and exercise routine. Many times, this can help a great deal in reducing the effects of arthritis.

Also, purebred dogs are generally more susceptible to arthritis, especially large dogs with a lot of weight put on their joints. Oddly shaped dogs, such as Dachshunds or beagles, are also more likely to have joint problems due to the stresses on their joints.

Avoiding Arthritis

Arthritis can be avoided with regular exercise, good diet and a careful eye for whenever your dog's range of motion decreases. It is inevitable as he ages, however, and will eventually be an issue that needs to be attended by a vet.

A number of medications are available to reduce pain and improve range of motion as your dog gets older, especially if he needs to exercise to keep his joints active.

Soft Tissue Trauma

Dogs can get injured just as easily, if not more so than we do. They get wound up, they play around, and they ultimately get injured because of that excitement if you're not careful.

Soft tissue includes the muscles, tendons and ligaments surrounding the joints and bones and can be injured in any number of ways — through tweaks to the legs, running into objects or being hit by moving objects, such as cars or bicycles. The severity of the soft tissue damage will determine how strong the treatment needs to be, though surgery may be required.

Diagnosis

It is hard to diagnose soft tissue damage in dogs, because, again, they cannot simply tell you, "My ankle hurts." You will need to visit your vet and have X-rays taken to determine the source of their pain. Usually limping, yipping and immobility will accompany swelling of the area where the damage occurred.

Even if there is no actual bone damage on an X-ray, soft tissue damage is usually a common diagnosis when swelling and pain occurs around a joint or in a muscle. Often, the use of medicine and rest are needed to keep the dog off the affected joint until it can heal.

Treatment

The actual treatment your dog will need for soft tissue damage will vary based on your vet, the size of your dog and the severity of the injury. Usually mild bruising will be treated with anti-inflammatories, such as aspirin and carprofen, with improvement in as little as three-five days.

If the damage is more moderate with stretching, a splint may be added, and in the case of serious injury where the joint has been harmed or the ligament has ruptured, surgery is generally required.

Usually, after three-five days of evaluation with medication, the injury will be reassessed to determine if the dog needs to have surgery or a stronger medication.

Avoiding Injuries

The easiest way to avoid the common causes of soft tissue damage is to keep your dog under control. Don't allow him to run free off a leash, and make sure he stays within sight at all times. Puppies especially should be limited in where they can go, both inside and outdoors.

Cancer/Tumors

Like human beings, dogs are susceptible to a number of forms of benign and malignant cancers in their skin, bones and organs. Each type of cancer is different in its growth rate, symptoms and prognosis. Most cancers, however, are treatable in dogs if they are identified early enough, and many tumors that are found with routine screening are benign and can be removed without extensive treatment.

Warning Signs

Once a dog reaches 10 years of age, he has a nearly 50 percent chance of contracting some form of cancer. However, even younger dogs can develop tumors and cancers, and it is important that you watch for the variety of possible warning signs. The good news is that around 60 percent of all diagnosed cancer in dogs is benign — the result of fatty tumors that can be relatively easily removed.

The actual symptoms to watch for vary depending on the cancer type:

- **Abdominal** – Vomiting, diarrhea, weight loss, swollen abdomen, lethargy
- **Mammary** – Lump or swelling in mammary tissue (Dogs that are spayed before they have a chance to go into heat do not develop this form of cancer.)
- **Lymphoma** – Swollen lymph nodes, stops eating, lethargy, general illness
- **Testicular** – Lumps and lethargy (does not affect neutered males)

Additional symptoms include the presence of any quickly growing lump or spot with strange coloring on your dog, issues with eating or drinking, coughing, breathing problems, or blood in either urine, vomit or feces.

Who Gets Cancer

Any dog can develop cancer, though some breeds may be more susceptible than others. Additionally, unaltered dogs are far more likely to get cancer than those that are safely spayed and neutered at a young age.

Purebred dogs with long lines of inbreeding also tend to have higher tumor rates, though there is no link between those tumors and malignant cancer.

Avoidance and Treatment

Avoiding cancer is not always possible. There are some steps you can take to keep them safe though. First, avoid letting your dog get too much sun, as they are susceptible to skin cancer, just like us.

Additionally, make sure to have them spayed or neutered young. Avoid any unnatural, processed foods as well. Chemicals in their water, as well as in plastic bowls or toys, can also be possible sources of the carcinogens that lead to cancer.

There is no medically proven link between specific things in a dog's diet or play habits that lead to cancer, however, so exact avoidance is hard. Once a dog is diagnosed with cancer, the tumor will be removed with an immediate surgery, followed by possible treatment with chemotherapy if it persists.

Eye Infection

Dogs don't have hands, which makes it pretty tough for them to wipe their eyes clean of the goop and crud that can build up over time. Toss in a little bacteria from the ground or their own bodies, and they can develop eye infections that lead to redness, swelling and discharge.

Warning Signs

Eye infection will be preceded by a number of warning signs, including discharge that is often thick and discolored, along with red and swollen eyes. They may also suffer from bloodshot eyes and will appear to be squinting, often pawing at their eyes, which can make it worse.

Keep in mind, however, that a dog with inhalant allergies can also suffer from similar symptoms. Either way, a trip to the vet can help you determine which route you're dealing with.

Who Gets Eye Infections

Some dogs are more likely to get eye infections than others. Breeds that have tear-straining include Maltese, Lhasa Apso, Shih Tzu and similar small dogs. Normal eye discharge and excess fur around the eyes are both issues that can lead to further infections.

Avoiding Infections

To avoid infections, keep your dog's eyes clean, wiping away the normal discharge that comes from their eyes each day. Also, groom their faces each day to avoid any fur matting.

If your dog gets an eye infection, take him to the vet for antibiotic treatment. Also, if the infection is conjunctivitis, you may need to have other pets in your home treated, as it is highly contagious.

Congestive Heart Failure

Another common health problem that strikes both humans and dogs is congestive heart failure. The disease can be caused by a number of factors, including genetics, heredity and environment. The result is a weakening of the heart that can lead to a drop in blood pressure and the ability to safely pump blood through the body.

Warning Signs

Most often, there will be no immediate symptoms of congestive heart failure. A heart murmur or weakened heart beat may accompany your dog's annual physical, leading to additional testing to rule out possible disease. Your vet will likely perform heartworm testing to rule out the possibility of infection. He will also check the lungs and abdomen for excess fluid and see how blood flow is maintained in his gums.

If the dog suffers from more advanced heart failure before diagnosis, he may have a dry cough that gets worse when he is resting, a lack of energy to play and general lethargy with increased breathing while at rest.

Who Gets Heart Failure

Congestive heart failure in a dog is more common as he ages. While some younger dogs can get the disease due to things like heart worm, the majority of naturally occurring CHF is due to a gradual breakdown of the heart muscle leading to failure.

Avoiding Heart Failure

As your dog ages, make sure to keep him as active as is comfortable and keep a close eye on his food. Avoid anything that might lead to obesity in your dog, and make sure he is only fed two or three times a day with the recommended daily allotment of food.

Excess pressure on his body from too much food or too little exercise can be major contributing factors. Additionally, if you live in an area with heartworm-carrying mosquitoes, make sure to have your dog tested annually and treated with monthly heartworm medication.

Hip Dysplasia

Of all the diseases your dog may suffer from, one of the most frustrating is hip dysplasia. It strikes dogs at any age, oftentimes as young as 2 years. The disease is orthopedic in nature and will lead to the abnormal formation of the hip, which then causes looseness in the joint and cartilage damage. The result is severe, early-onset arthritis that can make movement by your dog much tougher.

Warning Signs

Hip Dysplasia will be preceded by a drop in energy levels, difficulty standing or moving and a lameness in your dog's back legs. Your dog will stop wanting to use the stairs, especially when going up them, and will rarely want to stand up on his back limbs or jump up on anything.

He will start hopping with his back legs to walk and will show signs of soreness when he lies down, especially after heavy exercise. If your dog shows any of these signs, regardless of his age, it's important to get him to the vet for X-rays as soon as possible.

Who Gets Hip Dysplasia

Dysplasia is a genetic disease that passes down through a specific lineage of dogs. If you have two loose-hipped dogs mate with each other, the result is often a dysplasia-stricken puppy. Of course, not all dogs with the disease suffer from it or show symptoms, so it can be hard to determine if your new puppy has inherited it.

There are some environmental factors as well, including obesity, too much protein in food (such as in cat food), or too many vitamins and minerals. Things that are designed to make puppies grow faster have been shown to increase the risk of dysplasia and arthritis as well.

Treating Dysplasia

There are quite a few ways to treat dysplasia. More conservative, non-invasive treatments include weight loss, pain medication, physical therapy and basic exercise routines to work the hips.

If the disease has grown to a severe enough state, surgery may become an option instead of simple treatments. In one method, the veterinarian will attempt to slow the spread of arthritis, while other methods will work to salvage the degenerating hips before they can get too worn by the disease.

The only real way to know which treatment is best for your dog is to see a vet and have the necessary X-rays and tests done to determine the extent of his dysplasia. A vet will then determine what works best to treat those particular issues.

Obesity

Much like people, simple obesity is one of the most serious health problems that dogs get. As many as 40 percent of domestic dogs suffer from obesity, and the worst part is that almost all of it is preventable.

However, when a dog is allowed to remain obese for an extended period of time, he will start having trouble with basic exercise, develop breathing problems and in the long-term, might suffer from diabetes, heart disease or organ failure.

Warning Signs

Dogs that eat even 1 percent more calories than they need can suffer from obesity within just a few short years. To treat obesity, you must maintain a careful, healthy diet over time. Most of the time, it is hard to recognize a dog is overweight without checking his weight at the vet and getting perspective on what he is supposed to weigh. However, severe obesity will come with symptoms, such as lethargy, breathing difficulties, coughing or excess appetite.

Causes of Obesity

Obesity is caused purely by eating too much and exercising too little. There are additional diseases that can cause obesity, so it is good to see a vet if your dog is having trouble losing weight.

Most of the time, however, the simplest routine is to reduce caloric intake, cut feedings back to set times throughout the day and removing all table scraps and treats. Additionally, make sure your dog gets the daily exercise he needs to maintain his weight level and not get too fat.

Fiber and water intake are also good to keep his bowels and digestive process moving. You should weigh your dog regularly to check his progress and see a vet on a regular basis to ensure no health issues are developing.

Diabetes

Diabetes in dogs is the same as it is for human beings — the result of a deficiency in the insulin hormone, causing a decrease in their ability to metabolize sugars in their blood. It is the single most common endocrine disease dogs can get and comes in two forms, the same as for human beings.

Type I diabetes is when the body does not produce enough Insulin. Type II diabetes is when the body stops being able to use insulin effectively to process sugars. Almost all dogs get Type I diabetes, with very few cases of Type II ever reported.

Warning Signs

Your dog will start to show a number of symptoms when diabetes becomes an issue. He will grow excessively thirsty; will need to urinate more often; will lose weight, despite how much he eats; may become suddenly blind; and will grow lethargic and lose body definition in his muscles.

To actually diagnose diabetes, your vet will need to do a full physical to check for a urinary tract infection and to check other factors, such as glucose levels, blood count and the pancreatitis. A number of other diseases must first be ruled out before diabetes can be fully diagnosed.

The Causes of Diabetes

There is no prevention method for diabetes Type I; it is almost entirely genetic. The hereditary factors that lead to it are hard to pinpoint, so determining if your dog is likely to contract it is hard. Simply keep a close eye on his habits and watch for symptoms.

Treating Diabetes

Once your dog is diagnosed with diabetes, you will need to start providing a twice-daily injection of insulin. There are some oral medications as well, but most of them will require that the pancreas is still working to some degree.

In addition to the insulin, you'll want to maintain his weight with a high-fiber diet, regular exercise and absolutely no outside foods. There are also certain drugs, like steroids, that need to be avoided in a diabetic dog.

Dental Disease

Dogs can't brush their own teeth, and as a result, they can easily suffer from periodontitis or dental disease from the spread of bacteria in their gums. Periodontitis is the single most common type of infectious disease in dogs and is generally spread by the bacteria in plaque, especially when not properly controlled by regular brushing and cleanings.

It can lead to tooth loss, jaw fracture and other diseases as the bacteria are ingested with food on a daily basis.

Warning Signs

There are a number of signs of periodontitis. For starters, a dog will have bad breath, usually followed by bleeding gums. With just these symptoms, the disease can still be stopped and treated relatively easily. However, once it develops further, other symptoms might include tooth loss, tooth extrusion, ulcers in the mouth, gum recession and poor appetite due to pain.

Actually diagnosing the disease starts with a full medical workup and a mouth X-ray to check the total health of the dog's teeth. Because 70 percent of the teeth are below the gum line, it is important to see what is happening down there. Usually, general anesthesia is required to do a full dental work up.

Treating Dental Disease

After diagnosis, the dental disease is treated with antimicrobial drugs, antiseptics and a series of dental procedures, such as ultrasonic scaling, root planning and pocketing in the teeth to remove the affected areas. In severe cases of bone loss, extraction will be required to stop the spread of the disease through your dog's mouth.

Avoiding Infections

The easiest way to avoid dental disease in your dog is to brush his teeth daily with a pet dental product. You should also have his teeth checked every six months or so by the veterinarian. If your dog does not allow the checking of his teeth, it may be less frequent.

Gastroenteritis

Gastroenteritis is a general term that applies to any inflammation of your dog's intestinal lining or stomach. The causes can range greatly from simple anxiety or food change to a severe disease or parasitic infection. Usually, severe digestive symptoms will appear along with the gastroenteritis and will persist until treatment is administered.

Warning Signs

A dog with a stomach issue will usually have acute vomiting or diarrhea that lasts for a number of days along with dehydration, depression, blood in the stool or vomit and lethargy.

Keep in mind that if your dog vomits or has diarrhea occasionally, it is not a direct sign of gastroenteritis. It could merely be something he ate, but if it persists, it very well may be a disease or infection that needs to be treated immediately.

Who Gets Gastroenteritis

Gastroenteritis can be caused by a number of factors. Eating foods that are not healthy for dogs is usually a first stop for most vets in diagnosis. He may also be allergic or intolerant to a specific food, such as corn or wheat, or it could be the result of a toxin or specific infection.

Other possible issues could include blockages or obstructions (which must be treated immediately), metabolic issues with kidneys or the liver, bowel disease, ulcers, cancer, pancreatitis or other abdominal diseases.

Treatment

The most common treatment for gastroenteritis is to ensure that the dog gets the electrolytes needed to supply nutrients to the body and keep it hydrated. Food is usually withheld for 24 hours to reset the dog's digestive tract, and when it is reintroduced, mild, bland food with rice and boiled chicken are used to get your dog's digestion back on track. There are also drugs that can soothe the digestive tract or others that will stop diarrhea or vomiting.

The easiest way to avoid stomach issues from environmental sources is to limit what your dog eats and what he has access to. Keep your garbage out of reach; don't feed him table scraps, and feed him mild foods that are not too rough on his body.

Pancreatitis

When the pancreas becomes suddenly inflamed and activates various enzymes that start digesting itself, pancreatitis develops and can cause a number of advanced health issues in your dog.

The pancreas produces bicarbonate to reduce stomach acid, as well as other enzymes to help in digestion. There are no set reasons for why a dog might develop pancreatitis, but general causes are usually related to poor diet and obesity.

A dog that eats a high-fat diet, has liver disease or has recently been under for surgery or been subject to whole body infections is more likely to contract the disease.

Warning Signs

Warning signs and symptoms for pancreatitis vary greatly. Most dogs with pancreatitis will experience a loss in appetite, followed by severe lethargy and possible vomiting or diarrhea.

Signs of pain and fever are also common, along with general weakness and disinterest in playing or being active. Because these symptoms are so much like many other diseases, it is very important to see a vet immediately for a proper diagnosis. It could be as simple as food poisoning or as severe as pancreatitis.

Actual diagnosis is done by checking blood counts and doing a number of chemical tests to check for the enzymes emblematic of pancreatitis.

Treatment of Pancreatitis

If your dog is diagnosed with pancreatitis, know that it can be immediately life threatening and should be treated right away. Food and water are often withheld for as long as 72 hours, followed by subcutaneous or intravenous fluid administration. When food and water are reintroduced, it is done very gradually to see how the dog responds.

If the dog does not vomit for 24 hours, the food will be increased with fat reintroduced. Dogs are also held in a crate to keep them from moving if they have pain, and if there is an infection, antibiotics will be administered.

It's hard to prevent pancreatitis because it is hard to pinpoint an exact cause. The easiest ways to avoid the factors that lead to the disease are to reduce the fat in their diet and help them lose excess weight if they are obese. Do not feed them table scraps, keep sodium levels low and get them exercise on a daily basis.

Kidney Failure

Throughout all dogs there is a risk of chronic kidney failure. When it happens, the body is no longer able to remove the wastes from the dog's body in the form of urine, and toxins will start to build up, which can lead to a number of symptoms.

Warning Signs

Dogs that might be suffering from kidney failure will often show an increased thirst followed by excessive drinking and increased urination. They will also show severe lethargy and may even start vomiting with a strong, fetid odor in their vomit and their normal breath. They will also stop eating as much and show signs of weakness as a result. They could also show signs of depression and may lose general coordination while walking.

Who Suffers From Kidney Failure

While all dogs can suffer from kidney failure, certain breeds are more susceptible than others. Breeds with high kidney failure rates include:

- Bull Terrier
- Cocker Spaniel
- Samoyed
- Lhasa Apso
- German Shepherd
- Shit Tzu
- Cairn Terrier
- Norwegian Elkhound
- Golden Retriever
- Wheaten Terrier
- Doberman Pinscher

Additionally, there are a number of factors that can lead to kidney failure, including excess toxins in the body, bad blood flow, infections, various inflammations, cancer or other immune system problems.

Treatment for Kidney Failure

There is not an actual cure for kidney failure, but early diagnosis can help in treatment. Usually, treatment includes advanced fluid therapy, careful management of blood abnormalities with IV drugs, special diet with phosphorous and protein restrictions, as much water as the dog can drink and special care to make sure he has everything he needs. He may also need anemia management and vomiting control with special drugs.

It is generally not recommended that you treat your dog at home for renal failure; you should see a vet immediately.

There are no known ways to prevent renal failure. Make sure your dog can urinate and drink as much as he needs to, and avoid any situations where he has access to ethylene glycol — a contributor to renal failure.

Kennel Cough

Kennel cough is an infectious disease that causes heavy, honk-like coughing in your dog that can be highly contagious and very dangerous if not treated immediately. In fact, it is so dangerous that most kennels and boarding locations require vaccination from it before they'll keep your dog overnight.

Dogs most likely to obtain kennel cough are those that have been held in locations with a number of other dogs. Young dogs and puppies are especially susceptible to the cough, as they can get sick much faster and more severely.

Warning Signs

There are a number of signs that your dog has contracted kennel cough. The first is the upper respiratory symptoms, such as irritated eyes, runny nose and sneezing. They will then develop the signature cough — a loud cough that sounds like a honk. It will get worse when he gets excited or active and will appear as though he has something stuck in his throat. He might even vomit lightly or cough up fluid with severe bouts. If he develops pneumonia as a result, he will show signs of fever and depression as well.

Other symptoms include general depression, breathing problems, loss of appetite and fever. If you see even one of these symptoms, it's time to see your vet immediately.

A veterinarian will use chest X-rays to check for pneumonia, as well as basic blood tests and fecal tests to rule out the chance of a parasite.

Treating Kennel Cough

Kennel cough itself is not necessarily all that dangerous as it is akin to the human cold in that it will eventually die off and is not treatable with antibiotics. However, it can lead to infections, such as pneumonia, so it should be treated at least mildly to keep it from spreading.

Cough suppressants, antibiotics for dogs that have developed infections, and at times, anti-virals are given to treat the cough. At home, you will need to keep your dog away from other dogs, minimize his exercise, get him plenty of fluids and open his airway by removing his collar and giving him plenty of room inside.

Prevention can be optimized with the kennel cough vaccine. Even without the vaccine, you can limit his exposure by keeping him away from large groups of unvaccinated dogs and by de-worming dogs from a young age.

Epilepsy

Dogs can suffer from epilepsy and seizures in a number of forms. The actual cause of epilepsy is still unknown and can be either genetic or can develop over time with unknown environmental factors.

There are a number of ways a dog might have a seizure. He could look far away and twitch lightly, or he could fall to the ground with his whole body shaking, barking and even defecation and urination.

A seizure will usually happen with no warning and can last for as long as a few minutes, and there is no known link between seizures and particular breeds of dogs.

What to Watch For

A seizure will consist of three specific things:

- **Aura** – There will be small signs of a seizure about to happen, including whining, shaking, wandering, hiding or general restlessness. They may last for hours before a seizure occurs.
- **Ictus** – This is the actual seizure, and it can last for a wide duration. Generally, the dog will lose control of his body during this time.
- **Postictal** – After a seizure, a dog will appear disoriented and will start wandering or pacing. He may remain unresponsive and continue salivating for some time. This could last for days in some cases.

Do not feel like you should be able to recognize the symptoms of a seizure before it occurs. In some dogs, it's impossible to know when it's about to happen.

Handling a Seizure

When a seizure occurs, you should not panic because your dog is not suffering. Make sure to time how long the seizure lasts, and record it for the vet. Make sure to move any objects away so the dog cannot hurt himself, and take note of what the dog does or moves during the seizure for your vet's notes.

If the seizure lasts beyond five minutes, you need to call an emergency vet immediately.

Note: Don't worry about your dog swallowing his tongue. They don't do this, and you will likely get bit or block his airway if you try to put something in his mouth.

Treatment

If it is the first seizure, see a vet with the data you recorded. If your dog does not recover after a seizure within a half hour, contact the vet and follow his directions.

There are drug treatments for epilepsy, including Phenobarbital, diazepam and bromide — all for different levels of seizures. Your vet may also give specific at-

home restrictions, including diet and exercise guidelines. Make sure you keep up-to-date with your vet whenever a seizure occurs.

The Shocking Truth About Commercial Dog Food Revealed

<http://www.dogtrainingword.com/go/dogfood>

In this thought-provoking video, you will see exactly how many commercial dog food brands are killing pets all over the world.

See the evidence based on veterinary medical research that shows that any dog that eats commercial dog food is at a much higher risk of dying prematurely.

But don't worry, this video isn't all scary stories; there are also practical and proven solutions that you can start adopting today. Just one of the simple solutions in the video shows you how you can increase the lifespan of your dog by up to 134 percent while saving you up to \$10,000 over the lifetime of your dog.

Check out the video now, and prevent your dog from suffering an early and painful death:
